Kinematics (1/2)

A 3R robotic arm can follow a trajectory in a 3D space associated with the global coordination system $X_0 Y_0 Z_0$ marked in Fig. 1. Placement of the manipulator mount point is in $X_b Y_b Z_b$.

Transformations from $X_0 Y_0 Z_0$ to $X_b Y_b Z_b$ is defined as

$$A_0^b = \text{Trans}(X, a) \text{Trans}(Y, b) \text{Trans}(Z, c). \quad (2)$$

Kinematics (2/2)

End of the 1st manipulator link is in relation to global coordination system $X_0 Y_0 Z_0$ expressed as

$$A_0^1 = A_0^b Rot(Z, q_1) Trans(X, l_1). \quad (3)$$

The 2nd link location is described as

$$A_0^2 = A_0^1 Rot(Z, q_2) Trans(X, l_2) Rot(X, \frac{\pi}{2}). \quad (4)$$

The position of 3rd link, the end effector, is presented in the following relation

$$A_0^3 = A_0^2 Rot(Z, q_3) Trans(X, l_3). \quad (5)$$

The manipulator dynamics can be expressed as [5]

$$M\ddot{q} + C\dot{q} + D + T = u \quad (6)$$

where

- $M \in R^{n \times n}$ is an inertia matrix,
- $C \in R^{n \times n}$ is a Coriolis and centrifugal forces matrix,
- $D \in R^n$ is a gravitation vector,
- $T \in R^n$ is a friction vector,
- $u \in R^n$ is an input control vector.

Properties of the dynamics model [2]:

- 1 The M matrix is symmetric ($M = M^T$) and is positively defined ($M > 0$). It means that all eigenvalues of M are positive. Thus, the M matrix is invertible and not singular.
- 2 There is a skew symmetry between M and C .

$$\dot{M} = C + C^T \quad (7)$$

Dynamics (3/7)

To calculate inertia matrix M we have to calculate kinetic energy for each link. It can be calculated with following formula

$$E_i = \frac{1}{2} \text{tr} \{ \dot{A}_0^i J_i (\dot{A}_0^i)^T \} = \frac{1}{2} \dot{q}^T Q_i \dot{q}. \quad (8)$$

The J_i is a pseudoinertia matrix of i^{th} link and the Q_i is inertia matrix for i^{th} link.

J_i can be calculated in following way

$$J_i = \begin{bmatrix} \int_{L_i} x^2 dm & \int_{L_i} xy dm & \int_{L_i} xz dm & m_i \bar{x}_i \\ \int_{L_i} yx dm & \int_{L_i} y^2 dm & \int_{L_i} yz dm & m_i \bar{y}_i \\ \int_{L_i} zx dm & \int_{L_i} zy dm & \int_{L_i} z^2 dm & m_i \bar{z}_i \\ m_i \bar{x}_i & m_i \bar{y}_i & m_i \bar{z}_i & m_i \end{bmatrix}. \quad (9)$$

The integrals are the inertia moments calculated at the end of the link while $(\bar{x}_i, \bar{y}_i, \bar{z}_i)$ is the placement of the center of mass of the link in local coordinate system.

Thus, the inertia matrix M of the system is a sum of inertia matrices of each link

$$M = \sum_{i=1}^n Q_i. \quad (10)$$

The Coriolis matrix can be calculated from the inertia matrix M by using the Christoffel symbols of first kind. $C \in R^{n \times n}$ and each element of the matrix is equal to

$$C_{ij}(q, \dot{q}) = \sum_{k=1}^n c_{kj}^i(q) \dot{q}_k,$$

where

$$c_{kj}^i(q) = \frac{1}{2} \left(\frac{\partial M_{ij}}{\partial q_k} + \frac{\partial M_{ik}}{\partial q_j} - \frac{\partial M_{jk}}{\partial q_i} \right). \quad (11)$$

We can calculate gravity vector D with following formula [4]

$$D_i = - \sum_{k=i}^n m_k \left\langle g, \frac{\partial A_{0i}}{\partial q_i} R_i \right\rangle \quad (12)$$

where $g = [g_x, g_y, g_z, 0]^T$ and $R_i = [\bar{x}_i, \bar{y}_i, \bar{z}_i, 1]^T$.

Dynamics (7/7)

Lastly, to calculate friction forces in the manipulator joints we can use Tustin friction model [1]

$$T(\dot{q}) = T_v \dot{q} + T_s \operatorname{sgn}(\dot{q}) \quad (13)$$

where T_v is a viscous friction coefficient while T_s is a static friction coefficient.

Implementation

However, the non-linear function $\operatorname{sgn}()$ should be replaced rather with $\tanh()$ or $\arctan()$ because of computation reasons based on

$$\lim_{x \rightarrow +\infty} \tanh(s_c x) = \operatorname{sgn}(x) \quad (14)$$

where $s_c > 0$ and defines how closely $\operatorname{sgn}(x)$ is approximated.

Motivation

Input-output decoupling is a method which enables one to control end-effector's trajectory. In other words, it translates desired trajectory given in task coordinates like (X_0, Y_0, Z_0) into joint space q .

What is more, the input-output decoupling can be used instead of inverse kinematics.

Algorithm (1/5)

Let

$$y_i = k_i(q), \quad i = 1, \dots, n \quad (15)$$

where $k_i(q)$ is i^{th} element of end-effector kinematics vector.

Then

$$\dot{y}_i = \frac{d}{dt}k_i(q) = \frac{\partial k_i}{\partial q} \frac{dq}{dt} = J_i(q)\dot{q}. \quad (16)$$

The time derivative of above equation gives

$$\begin{aligned} \ddot{y}_i &= \frac{d^2}{dt^2}k_i(q) = \dot{J}_i(q)\dot{q} + J_i(q)\ddot{q} \\ &= \dot{q}^T \frac{\partial^2 k_i}{\partial q^2} \dot{q} + J_i\ddot{q} = P_i + J_i\ddot{q}. \end{aligned} \quad (17)$$

Algorithm (2/5)

By collecting all output variables we obtain a following matrix equation

$$\ddot{y} = P + J\ddot{q}. \quad (18)$$

Let's consider dynamics of the manipulator (6). The real inertia matrix M is always positively defined, therefore we can reformulate (6) to

$$\ddot{q} = M^{-1} (u - C\dot{q} - D - T). \quad (19)$$

After substitution of dynamic equation (19) to (18) it yields

$$\begin{aligned} \ddot{y} &= P + JM^{-1} (u - C\dot{q} - D - T) \\ &= P - JM^{-1}C\dot{q} - JM^{-1}D - JM^{-1}T + JM^{-1}u. \end{aligned} \quad (20)$$

Algorithm (3/5)

The equation (20) is an affine system with following equation

$$\ddot{y} = F + Gu \quad (21)$$

where

$$F = P - JM^{-1}C\dot{q} - JM^{-1}D - JM^{-1}T, \quad (22)$$

$$G = JM^{-1}. \quad (23)$$

We assume that G is square and invertible. Therefore, the J has to be square and invertible, too.

Algorithm (4/5)

Injecting the control law given below as

$$u = G^{-1}(-F + v) \quad (24)$$

to the affine system (21), where v is a new input to the system, we obtain the closed-loop system expressed in the form of double linear integrator.

$$\ddot{y} = v.$$

Algorithm (5/5)

To ensure that the desired trajectory is followed with end-effector by moving only its joints we propose PD controller with correction

$$v = \ddot{y}_d - K_d \dot{e} - K_p e \quad (25)$$

where y_d is a desired trajectory of the end-effector, $K_p = K_p^T > 0$, $K_d = K_d^T > 0$, and the system error is defined as $e = y - y_d$ and its time derivative equals to $\dot{e} = \dot{y} - \dot{y}_d$.

To ensure that the procedure of input-output decoupling is possible, the necessary condition defined by Isidori has to be met [3]. It says that the number of inputs to the system has to be equal to the number of system's outputs.

Figure: Real and desired trajectory

Matlab

Model of dynamics is defined as a set of 1st order differential equations. It means that instead of simulating dynamics which is given as

$$\ddot{q} = f(q, \dot{q}, t)$$

we have to rewrite equations to a set of 1st order differential equations, e.g.

$$q_{d,0} = q,$$

$$q_{d,1} = \dot{q}_{d,0},$$

$$q_{d,2} = \dot{q}_{d,1},$$

$$\vdots$$

$$q_{d,n} = \dot{q}_{d,n-1},$$

$$\dot{q}_{d,n} = g(q_{d,0}, q_{d,1}, \dots, q_{d,n-1}, t).$$

Ordinary differential equation (ODE) (1/2)

Calling ODE solver in Matlab can be done with following instructions

```
1 modelNameFun = str2func('model');  
2 opts = odeset('RelTol',1e-6,'AbsTol',1e-6);  
3 opts = odeset(opts,'OutputFcn','odeplot');  
4 [t, yououtput] = ode45(@(t,y) modelNameFun(t,y,parameters), ...  
5     [0:sample_time:tEnd], ic, opts);
```

Ordinary differential equation (ODE) (2/2)

The model function should comply with requirements of an ODE function model.

```
1 function [ output_args , additional ] = model( t , input_args ,  
        parameters )  
2 qr_d1 = input_args(1:3);  
3 qr = input_args(4:6);  
4 % ...  
5 output_args = zeros(6,1);  
6 output_args(1:3) = qr_d2;  
7 output_args(4:6) = qr_d1;  
8 additional.param = param1;  
9 additional.vector = vector1;
```
